Output Graphs:

RESULT:

The continuous-time Fourier transform of representative signals was successfully obtained using FFT-based approximation, and their magnitude and phase spectra were analyzed to identify significant frequency components. The time-shift property was verified by comparing the computed and theoretical Fourier transforms, confirming that time shifting preserves magnitude while introducing a frequency-dependent phase shift. The spectral components and occupied bandwidth of a composite communication signal were also determined, demonstrating the importance of frequency-domain analysis in communication-system design.
